Open biomass burning (BB) is a major natural source of absorbing aerosol species (BC and BrC) that affect the Earth's radiation budget. However, BC emission data for remote regions (such as Siberia) have been poorly evaluated against atmospheric observations.

➢ Can satellite retrievals of absorption AOD (AAOD) provide useful constraints for BC emissions?

➢ Are the available BC emission estimates for Siberia consistent with satellite observations?

➢ Can sources of BrC from fires be evaluated using the same top-down methods as BC emissions?

18th GEIA Conference, Hamburg, Germany, 13-15 September 2017
Method: using the AAOD and AOD satellite observations to constrain the EC / OC ratio in BB aerosol

**A problem:** simulations of AAOD with CTMs are too uncertain

In this study, a robust empirical relationship between EC/(EC+OC) ratio and SSA from the FLAME-4 analysis [Pokhrel et al., ACP, 2016] was used:

$$SSA^\lambda \approx a^\lambda - b^\lambda \frac{[EC]}{[EC]+[OC]} \quad a, b \approx 1$$

**Analysis of AERONET observations at Siberia [Konovalov et al., 2017]:**
- Level 2 SSA, AAOD and AOD data from the Tomsk-22 and Yakutsk sites for summer months of 2012 were considered.
- Using simulations with the CHIMERE CTM, we selected the measurements corresponding to dry conditions (RH<60% in BB aerosol columns)

$$\frac{AAOD_{388}}{AOD_{550}} = 1.98(\pm0.19) \frac{[EC]}{[EC]+[OC]} + 0.018(\pm0.008)$$
Method: using FRP measurements and model data to constrain BC (EC) emissions

Input data:
- MODIS FRP observations (Level 2 MYD14/MOD14 V6 data product)
- CHIMERE CTM simulations (AOD, BC and OC columns…)
- MODIS AOD at 550nm (Level 2 MYD08/MOD08 V6 data product)
- OMI AAOD at 388 nm (OMAERUV v006 Level 2 data product)

\[ E^s(t) = \Phi_d \sum_l \alpha l \beta^s_l \rho_l h_l(t) \]

\[ E^s \] is the emission rate of the species \( s \);
\( \Phi_d \) is the daily mean FRP density;
\( \alpha \) is the FRP -to- biomass burning rate conversion factor;
\( \beta_{sl} \) is the emission factor

Inversion of AOD observations:
\[ \alpha_{opt} = \text{argmin}[J(AOD_o, AOD_m)] \]

Inversion of AAOD observations:
\[ AAOD_{m}^{388} = AOD_{m}^{550} \left( k_1 \frac{[EC]}{[EC] + [OC]} + k_2 \right) \]

\[ \beta_{EC}^{opt} = \text{argmin}[J(AAOD_o, AAOD_m)] \]

Estimation of uncertainties (bootstrapping)

Fires have been aggregated into the two categories: boreal forest fire and other fires (grass, agricultural etc.)

Results: Validation and effects of BB aerosol aging

The Enhancement Ratio ($\gamma_a$) for AAOD:

\[
\gamma_a(t_a) = \frac{\tau(t_a) - \tau_b(t_a)}{\tau_t(t_a)}
\]

- $\tau$: AAOD observations
- $\tau_b$: background (modeled) AAOD
- $\tau_t$: AAOD of a modeled aerosol tracer (no aging, no deposition)
- $t_a$: BB aerosol photochemical age

\[
\gamma_a(t_a) = \arg\min_{i,j\in n} \sum (\tau_o^{ij} - \tau_m^{ij})^2
\]

$n \in [1, N_a]$

Perspectives

➢ The current estimates of the BB impact on the radiation balance in the Northern Eurasia and in the Arctic may need to be revised

➢ A consistent representation of emissions, optical properties and atmospheric evolution of BB aerosol in models
